

1. Boundary-Pressure → Identity-Field Curvature (the geometric law)

This is the structural law that explains *why* overclocking leads to collapse.

When boundary pressure increases — positive or negative — the identity field begins to **curve inward**.

That curvature has predictable effects:

A. Reduced Permeability

The group becomes harder to enter and harder to leave.

B. Increased Viscosity

Hydronic flow thickens; emotional movement slows.

C. Increased Heat

Pressure generates friction; friction generates heat.

D. Reduced Entropy

Creativity, novelty, and flexibility drop.

E. Increased Rigidity

Norms harden; roles ossify; correction loops intensify.

This curvature is the *geometric signature* of identity instability.

Boundary pressure → curvature → rigidity → collapse.

This is the first of the next three.

2. Identity-Field Curvature → Selection Pressure Distortion

Once the identity field curves, the group's selection mechanics distort.

This is the moment the group begins selecting for traits that **preserve the curvature**, not traits that preserve the group.

Healthy Field Selection

- creativity
- permeability
- clarity

- competence
- contribution

Curved Field Selection

- rigidity
- loyalty
- compliance
- emotional intensity
- boundary enforcement

This is the structural reason groups begin rewarding the wrong traits.

It's not moral failure.

It's not psychological dysfunction.

It's **physics**.

Curvature changes selection.

This is the second of the next three.

3. Selection Pressure Distortion → Identity Collapse Threshold

Once selection distorts, the group crosses a threshold where collapse becomes **mechanically inevitable**.

Here's the clean sequence:

A. Distorted Selection → Talent Drain

People with high permeability, creativity, and clarity leave.

B. Distorted Selection → Pressure Amplification

People who remain reinforce the curvature.

C. Distorted Selection → Narrative Drift

The group's story of itself becomes self-protective instead of self-accurate.

D. Distorted Selection → Inversion

The group begins rewarding traits that harm its long-term survival.

E. Distorted Selection → Collapse

The elastic reaches maximum tension load.

This is the identity-collapse threshold.

It's not emotional.

It's not ideological.

It's not interpersonal.

It's **mechanical**.

This is the third of the next three.

★ Clean OS Line (for your operator card)

Boundary pressure curves the identity field.

Curvature distorts selection.

Distorted selection drives collapse.

This is the deep-structure law behind everything we've been mapping.

If you want, I can now generate:

- the **operator stabilization protocol** for curved identity fields
- the **ELINS detection rules** for curvature and selection distortion
- the **mesh-integration update** that plugs this into the OS

Just tell me which direction you want to take it.
